

Cross Domain Security

Data Guard

Secure data and file transfer between physically separated networks

Key Benefits

- › High-performance transfer sustains up to 8.5 Gbps (TCP), 5 Gbps (UDP), 6 Gbps (HTTPS) and secure file movement up to 200 Gb/hr
- › Provides highly customizable data validation rules for maximum flexibility rather than static, one-size-fits-all policies
- › Flexible software implementation for all environments: datacenter to SOC and meets austere, ruggedized SWAP-C requirements
- › Enables real-time video streaming while providing unparalleled control and auditing
- › Content disarm and reconstruction capabilities
- › Customer maintainable for simplified configuration and management
- › Common Criteria certified for EAL4+

Connecting the “unconnectable”

The persistent threat of cyberattacks, penetration and data loss require that only the most secure methods are used to maintain the highest standards of security, particularly in highly regulated industries. Many organizations struggle with how to balance protecting sensitive data while at the same time utilizing cutting edge collaboration and automation technologies. The common approach many organizations take is to separate sensitive data and networks from information technology systems and the internet. This is a good security practice, but on its own can leave systems vulnerable and prevent adoption of automation and cloud-based technologies.

Forcepoint Data Guard

Forcepoint Data Guard delivers this balance by enabling highly complex, bi-directional, automated data and file transfers between physically separated networks.

To provide defense-grade data control at scale, Data Guard leverages a trusted operating system and security policies that enforce role and process separation and isolation for automated, byte-level content inspection and sanitization, with customizable rules to handle even the most specialized data types and protocols.

Supporting today's security paradigms

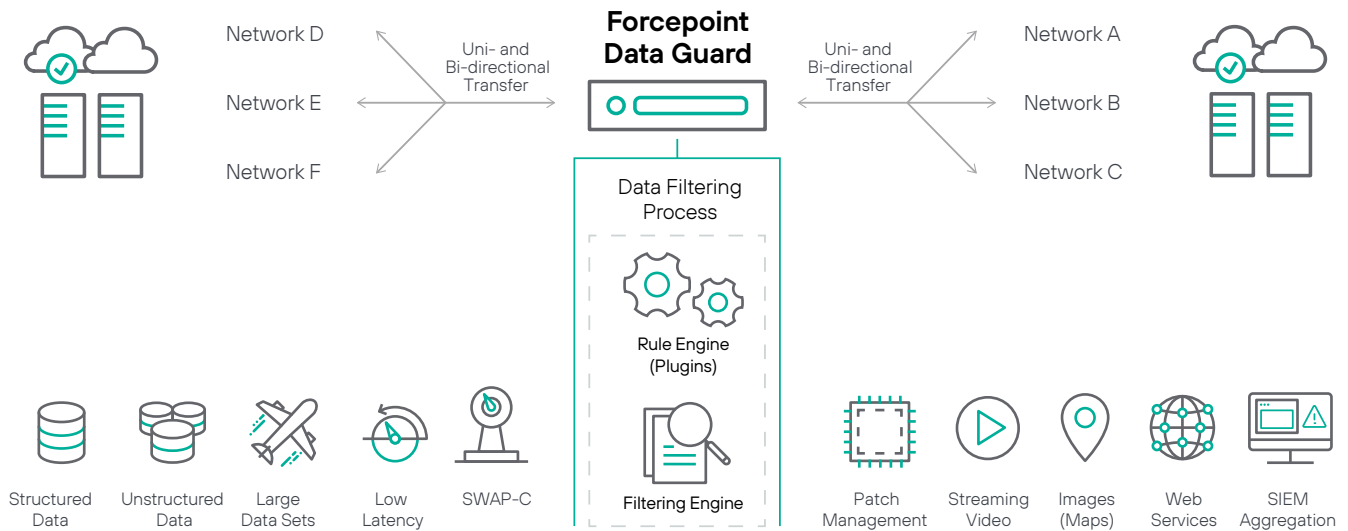

Data Guard enables secure data and file (structured and unstructured data) movement between segmented networks in uni-, bi-, or multi-directional fashion. The trusted operating system foundation derived from Red Hat Enterprise Linux with enhanced SELinux modules allows Data Guard to be used in highly regulated environments.

Ready for tomorrow's challenges

Data Guard is designed to evolve as the demands on your environment change. Thanks to its highly flexible and customizable rule- and policy-based structure, Data Guard ensures an enterprise's ability to monitor and control any future data types and devices.

Data Guard was designed for highly regulated environments such as government, military, critical infrastructure, law enforcement, and any other environment that must:

- Move sensitive data between separated networks
- Adhere to strict regulations for devices that move data between networks
- Utilize non-standard or non-typical data types and formats

A flexible approach

Data Guard is highly flexible in its secure approach to high assurance data movement through the robust security policies within adaptors, plugins, and the filtering process. The rule engine provides APIs to handle rich data types including: HTTP header, JSON, SOAP, MIME, compression, HTML, XML, file sanitization for Office, PDF, and images, streaming data, and the flexibility to secure most TCP and UDP protocols.

Filtering process

The Forcepoint Data Guard filtering process consists of built-in filtering capabilities: Rule Engine (plugins) and the Filtering Rules. Each capability provides consistent policy enforcement across all adaptors. Instead of pre-packaged point-and-click policies, the filtering process supports full customization of inspection capabilities that enable the creation of complex security policies. This allows specific inspections and constraints for each deployment rather than generic controls based on file type. Almost any security policy can be expressed through the user-configurable LUA interface language.

Forcepoint Professional Services works with each customer to determine which adaptor(s) and plugins best support use case requirements. Any combination of adaptors and plugins can be used to secure a flow. Data Guard supports multiple flows, with each flow managed independently without affecting other operational flows.

Adaptors

Data Guard Adaptors are service applications used to receive and transmit data from source and destination networks. When inbound, the adaptors terminate the network protocol. When outbound, they receive filtered data and send it out on to the appropriate network.

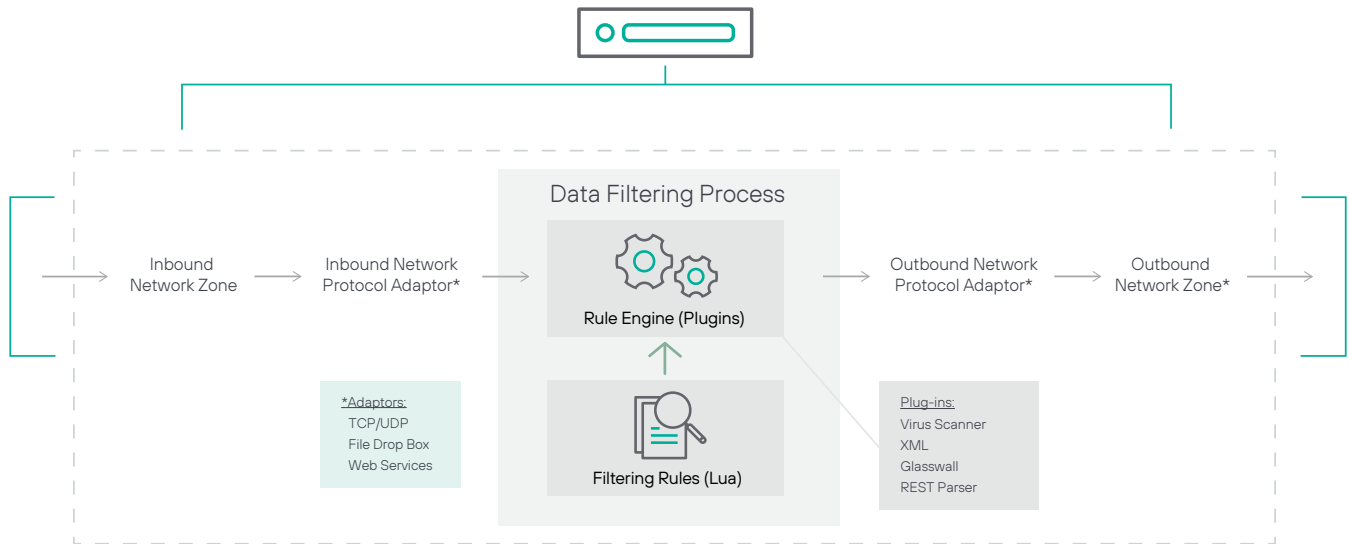

→ Generic TCP and UDP

Data Guard supports the transfer of most TCP and UDP based protocols. These adaptors are also used to create custom protocols to meet specific data requirements. The UDP adaptor can be used with multicast applications to securely bridge multicast domains or to convert multicast to unicast or vice versa.

→ Secure File Drop

The File Drop adaptor monitors directories on source servers and retrieves files for inspection and content filtering prior to dissemination to destination servers. Files that fail transfer due to policy violation can be quarantined on the source system for further analysis and review. The File Drop adaptor uses Secure Copy (SCP) to transfer files between the guard and external servers. The File Drop adaptor requires an optional feature license.

Forcepoint Data Guard

→ Web Services

The Web Services adaptor is a high-performance proxy for HTTP and HTTPS transfer protocols combined with the flexible rule engine enables modern infrastructures (particularly IT/OT) with secure transport communications and added capabilities for deep content inspection, sanitization and domain separation. The Web Services adaptor requires an optional feature license.

Plugins

Data Guard plugins are helper modules that assist with the data filtering process. Plugins simplify the filtering rules (in the LUA language) needed to perform data validation and transformation. All plugins require an optional feature license.

→ **Virus Scanner:** Integrated McAfee® Anti-Malware Engine for scanning block data or files, a top rated product for effectively detecting malware in real time.

→ **XML:** Parse, validate (schema and digital signature), and modify standards-compliant XML data types.

→ **Glasswall:** Sanitization and transformation of complex unstructured documents (e.g., Microsoft Office, PDF) to eliminate malicious threats in real time.

→ **REST Parser:** Parse and modify REST (JSON or SOAP) data. Allows for workflow creation to inspect and secure REST-based network communications. Widely used with modern microservices and web services.

→ **Video Streaming:** KLV checking, decoding and encoding of various video transport protocols (e.g., MPEG-TS, RTSP/RTP, HLS) and video frames (H.264, H.265) for security inspections.

→ **Utility Plugins:** Regex search, PKI and cryptography, file typing, file compression/decompression, HTML and MIME handling, JAR file validation, and more.
